

NEXUS 2.0 · enterprise target flow

Next-phase architecture only. Every box is the upgraded stack — role on the chip, library or protocol under it.

1 Touchpoints

Work arrives here. Slack is inbound only.

Nexus application · enterprise runtime

LangGraph runs the flow · A2A at the edge · MCP for tools · OIDC + RBAC on every call · Guardrails on model, tool and dispatch

2 Orchestration · LangGraph is the runner

The canvas still authors a JSON graph. At run time that graph is compiled into a LangGraph StateGraph and executed with checkpoints.

3 Five specialist skills · each skill is a LangGraph node

Skills still never call each other. They emit an A2A message. Guardrails sit on the model call, the tool call, and the formula.

4 What a skill can reach out to

Built-in writers stay. MCP and A2A are how new systems plug in. Guardrails sit in front of every write.

5

Assembly workbench

Design, test, then promote

6

Context fabric · RAG

Evidence a decision can cite

7

Assurance + drift

Operate the fleet, catch quality slip

8

Identity and policy

Wraps every call into the blue box

9

Runtime foundation

What the enterprise picture sits on. LangGraph checkpoints here; the API stays FastAPI.

Read it as a sentence: work arrives at a touchpoint including Slack (1). Requirements are typed, the JSON graph is compiled into LangGraph and run with checkpoints (2). Five skills execute as LangGraph nodes and hand A2A messages (3). Writers, SAP, MCP tools and remote agents are reached only after RBA C and guardrails (4). The workbench tests and promotes the flow (5). Hybrid RAG supplies cited evidence (6). OpenTelemetry plus a drift block watch quality (7). Identity and policy wrap every call (8). Kubernetes, Postgres, object storage and Vault sit underneath (9).
