

NEXUS 2.0 · how the application flows today

Follow the numbers. Every green element runs in the current build; amber is a thin version; grey is not written yet.

1 Touchpoints

Where work arrives and where the person stays in control

5

Assembly workbench

Where a flow gets built and packaged

- Chat and upload intake
- Generated config panel
- Canvas edit, then re-sync
- Preview and confirm (with a flame icon)
- Package into the library
- Dry run and replay (amber border)
developer suites only today

6

Context fabric

What the agent needs to know

- Parse and infer the schema
- Chunk the documents
- Extract typed facts
- Retrieval, RAG (amber border)
lexical scoring, not semantic
- Embeddings and vector store
- Knowledge graph and semantics
- Governed data products

2 Orchestration · understand, then assemble the flow

The model fills in values. The graph itself is computed in code, so the same answers always build the same flow.

3 Five specialist skills · the only things that ever touch the data

Each one is a boiler plate: a versioned behaviour file, a config schema, modes, and named exit ports.

4 What a skill can reach out to

Top row exists today. Bottom row is the open protocol work that would let any tool or outside agent plug in.

Nothing in this row fires on its own. Dispatch and write-back both wait for a person to click, and the click is recorded against the run.

9 Runtime foundation

Deliberately plain, with one swap seam left open where the file store is today.

7

Assurance and agent ops

Proof it worked, and the loop back

- Run trace per step
- Latency per step
- Structured logs
- Lineage and row explain
- Versioning (amber border)
no promotion workflow yet
- Evaluation and regression
- Drift, cost and alerts
- Release gates

8

Identity and policy

Would wrap every call above

- Single sign-on
- Authorization and scopes
- Acting-user propagation
- Policy enforcement point
- Execution sandbox

Read it as a sentence: work arrives at a touchpoint (1), the orchestration understands it and assembles a flow (2), five specialist skills execute that flow and hand a typed envelope to each other (3), a skill may reach a writer, a mailbox or a business system but only after a person clicks (4). The workbench builds and packages the flow (5), the context fabric supplies the evidence (6), assurance records what happened and feeds the next version (7), identity and policy are the missing wrapper (8), and it all sits on a plain runtime (9).
